Paging

A way to isolate process memory from each other and much more.

- Kernel development can be achieved in 1 week only
- Doing it properly can last... 3 months

Physical address

Real hardware address in your RAM.

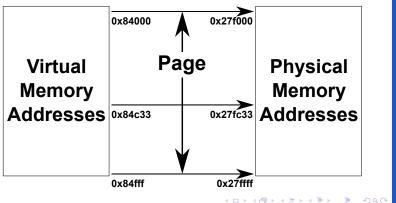

Virtual address

Address relative to an address space that are defined to point to physical ones.

The kernel is free to define what virtual address points to what physical one.

Page

Unit in memory that is the minimal memory portion mapped linearly from virtual to physical addresses. Its typical size is 4 KB or 0x1000 B in hexadecimal.

Mapping

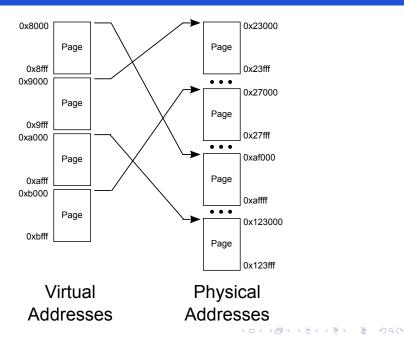

Linear virtual addresses corresponding to their linear or not physical addresses.

This is always expressed in unit of pages.

Address space

Set of mapping that is related to one process. Threads share the same address space.

Paging rights

Every page have the following rights:

- Write: allow writing this page
- Userland: allow userland to access this page

Read is always authorized.

NX flag

NX flag is a right that disable execution of page. It's a big security improvement.

No, some addresses above 0x7FFFFF are hooked by the CPU to do some hardware stuffs.

- Always suppose, you can use all the possible addresses from 0x0 to 0xFFFFFFF in 32bits.
- This is why having 4GB of RAM on 32bits computer is... useless.

No, your memory is managed by Page Tables that are too in memory.

Moreover, be careful because when you do a malloc in your memory management system it can trigger a mmap...

Question

What about the virtual addresses of the kernel?

Answer

- Kernel binary is mapped in all your User land processes in order to do syscalls
- Its address must be the same for all processes for performance reason
- On most 32 bits UNIX system, the kernel address space is above 0xC0000000

- Corresponds to a malloc but for pages
- All malloc algorithms can work for this allocator
- As for malloc, buddy algorithm is the best: O(1)
- This is the one chosen for Linux and mikro

- Every area has a buddy
- A buddy is found by xoring the address with the size of the element
- Every element needs the following metadatas:
 - Free/Used
 - Size of the element

Conclusion

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへで

- Typically metadatas are stored in the element itself reducing element storage space
- This cannot work for paging because a page:
 - starts at address + 0x0
 - ends at address + 0xFFF
- So no room for anything else

Metadatas in the cloud

Metadatas must then be stored elsewhere ...

Linux solution

- Metadata and all information about pages are stored in a big array
- Finding a page metadata is O(1)
- All pages are in the table so it takes a lot of memory

mikro solution

- Metadata and all information about pages are stored in the heap
- A big array of pointers is used to find page metadata
- Still O(1) but less memory is used
- This works because mikro needs less information about pages than Linux

Linux

Linux uses its slab allocator behind kmalloc.

mikro

mikro use an other buddy algorithm to allocate in the kernel. The usage of a slab for mikro is overkill.

Question

What happens if in the middle of my mmap code I trigger an other mmap through a malloc?

Answer

Kernel has a reserve of already mapped pages that are used in this particular case.

 mikro C++ new function can have a CRITICAL flag to ask for this.

• this reserve is checked prior to every mmap and new.

- mikro uses a bootstrap that is relocatable.
- Relocatable means it can execute properly at any address in memory.
- This bootstrap initialize paging and sets kernel above 0xC0000000.

- Copy kernel from zone DMA to zone Normal and set a better kernel address space.
- Initialize kernel allocator with a fixed set of pages to allow calling **new** during boot.
- S Fill computer reserved zones with what BIOS provides.
- Add kernel private areas to these reserved zones.
- Find room for paging metadatas and add it to reserved zones.
- Initialize physical and virtual allocator.
- Map kernel modules and command line.
- Switch to real kernel allocator.
- Do some cleanup.

The segfault aka page fault can be used to do funny things:

- File mapping optimisation:
 - When mapping a file into memory, instead of putting it all in memory, it's not mapped.
 - When a page fault occurs, it then reads from the disk and put it in memory.

Victor Apercé

Introduction

Hardware management on x86

• COW – copy on write – uses about the same mechanism:

- When a page needs to be copied for an other process, it's just shared with read right only.
- When the process wants to write to this page, a page fault occurs and the copy is done then.
